1. How can AI become a product or service?

In my PBL class, I learned how to build a Business AI model. My AI model can help people solve economic and business problems. When AI becomes a company's product or service, it can help customers solve different problems, such as finding products that match their needs or helping customers solve problems with a product. Therefore, AI is not only a tool for a company but can also become a product or service that creates value for customers and generates additional revenue for the company.

2. Possible AI services

There are many ways AI can help semiconductor companies. AI Chip Inspection allows companies to quickly check the condition and quality of chips. AI Defect Detection uses AI to identify defects in products or images and find problems quickly. Predictive Equipment Maintenance uses AI to predict equipment problems, helping companies solve issues earlier and reduce the costs caused by equipment downtime. Semiconductor Data Analysis analyzes large amounts of semiconductor production data to identify problems, risks, and opportunities for improvement. Production Optimization helps companies find more efficient ways to produce products, which can reduce production costs.

3. My selected AI services

I would prioritize Production Optimization and AI Defect Detection because they can help the company produce higher-quality products while increasing efficiency and reducing costs. Production Optimization can help the company find a more efficient production process, while AI Defect Detection can identify product problems before the products are sold to customers. I believe better product quality can attract more customers and potentially increase sales. By combining these two AI services, the company can improve its production process and increase the chance of producing better-quality products.

4. Who needs this AI?

My AI can provide quality and production support to other members of the company when they start producing products. Engineers, semiconductor manufacturers, wafer fabs, and testing and packaging companies could use this AI to work more efficiently. It can help employees complete more work in the same amount of time. For business owners, this can reduce labor and production costs. The company can also produce products faster while maintaining good quality, which can save both time and money.

5. How can it become a business service?

This AI would be suitable for integration into a semiconductor company because it can improve production efficiency and product quality. The company could use the AI internally or provide it

as a service to other semiconductor companies. By selling the AI service, the company could create an additional source of revenue. In the future, the AI could also be improved with more production data and better equipment, allowing the company to provide more accurate and efficient services to customers.
